

affluents

One payment in. Your money routes itself.

A programmable income router built on Arc

THE PROBLEM

The payment arrives; the work begins.

Freelancers paid by international clients receive money — then everything is manual.

Convert currency. Set aside tax. Remember to save or invest.

Good money habits fail at the moment of arrival.

THE PRODUCT

Share a payment link.
Your client pays USDC on Arc.
The payment routes itself.

Spend — auto-converted USDC → EURC

Reserve — USDC tax bucket

Earn — on-chain vault position

The invoice is the entry point — the routing is the product.

WORKING TODAY ON ARC TESTNET

Four invoices routed end-to-end. Not mocked, not local.

Money-handling rules, written down and tested.

Verifier branches by payment type: direct ERC-20, smart-account ERC-20, native.

Arc's 18-decimal EIP-7708 system logs filtered by emitter — never miscounted as 6-decimal amounts.

Documented 18→6 floor-and-dust rule at the native boundary.

Partial payments aggregate; overpayments are **held, never auto-routed**.

Intent-journaled, crash-safe pipeline — restarts reconcile, no double-spends.

29 unit tests, plus a deposit-wallet concurrency test.

Not garnish — the wallet layer, the gas, the settlement.

Arc — settlement layer · USDC-as-gas · sub-second deterministic finality

Circle Developer-Controlled Wallets (SCA) — the entire wallet layer: deposit pool + treasury, spend, reserve roles

Circle Gas Station — every sweep, transfer, and vault deposit sponsored; no wallet holds gas

USDC + EURC — pay in USDC, hold Spend in EURC; multi-currency by default
